

ABSTRACT

The present invention proposes a device for processing
fodder (8) comprising a rotor (15) driven in rotation
5 about its longitudinal axis (45), a first guide element
(19) partially surrounding the rotor (15), and a second
guide element (34) that is capable of occupying at
least two positions relative to the rotor (15).

10 The device (8) is remarkable in that a first control
member (24) is provided which is intended to move the
first guide element (19) into at least two positions
relative to the rotor (15) and, to hold it in these
positions, a link (39) is provided between the first
15 guide element (19) and the second guide element (34) so
that a change of position of the first guide element
(19) modifies the position of the second guide element
(34) and a second control member (44) is provided which
is intended to dispose the second guide element (34)
20 according to the various configurations.
